Reminders

- Course website: https://natanaso.github.io/ece276b
- ► Sign up on Piazza!
- ► Grading policy: 4 homeworks, 25% each
- Late policy:
 - 1 min to 7 days late: 10% penalty
 - more than 7 days late: 0 credit
- Assignments will be password protected
- First homework is out! Due Jan 30 at 4:59pm.

Notation and Terminology

$x \in \mathcal{X}$	state of the Markov process
$u \in \mathcal{U}(x)$	control/action in state x
$p_f(x' \mid x, u)$	motion model, i.e., control-dependent transition pdf

g(x, u)immediate/stage reward for choosing control u in state x $g_T(x)$ (optional) reward at terminal states x

 $\begin{array}{ll} \pi(x) \in \mathcal{U}(x) & \mbox{control law/policy: mapping from states to controls} \\ J^{\pi}(x) & \mbox{value function:$ **cumulative reward** $for starting at state x} \\ & \mbox{and acting according to } \pi \mbox{ thereafter} \end{array}$

 $\pi^*(x)$, $J^*(x)$ optimal control law and corresponding value function

Problem Formulation

• Motion model: specifies how a dynamical system evolves

$$x_{t+1} = f(x_t, u_t, w_t) \sim p_f(\cdot \mid x_t, u_t), \quad t = 0, \dots, T-1$$

- discrete time $t \in \{0, \ldots, T\}$
- state $x_t \in \mathcal{X}$
- control $u_t \in \mathcal{U}(x_t)$ and $\mathcal{U} := \bigcup_{x \in \mathcal{X}} \mathcal{U}(x)$
- motion noise w_t (random vector) with known probability density function (pdf) and assumed conditionally independent of other disturbances w_{τ} for $\tau \neq t$ for given x_t and u_t
- ► the motion model is specified by the nonlinear function f or equivalently by the pdf p_f of x_{t+1} conditioned on x_t and u_t
- Observation model: the state x_t might not be observable but perceived through measurements:

$$z_t = h(x_t, v_t) \sim p_h(\cdot \mid x_t), \quad t = 0, \dots, T$$

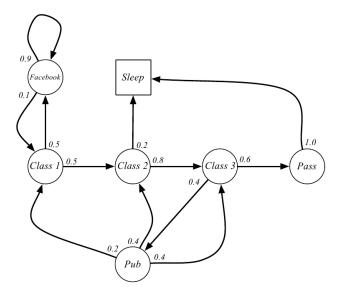

- ▶ measurement noise v_t (random vector) with known pdf and conditionally independent of other disturbances v_τ for $\tau \neq t$ for given x_t and w_t for all t
- the observation model is specified by the nonlinear function h or equivalently by the pdf p_h of z_t conditioned on x_t

Markov Chain

A Markov Chain is a stochastic process defined by a tuple $(\mathcal{X}, p_{0|0}, p_f)$:

- X is discrete/continuous set of states
- $p_{0|0}$ is a prior pmf/pdf defined on \mathcal{X}
- *p_f*(· | *x_t*) is a conditional pmf/pdf defined on *X* for given *x_t* ∈ *X* that specifies the stochastic process transitions. In the finite-dimensional case, the transition pmf is summarized by a matrix
 P_{ij} := ℙ(*x_{t+1}* = *i* | *x_t* = *j*) = *p_f*(*i* | *x_t* = *j*)

Example: Student Markov Chain

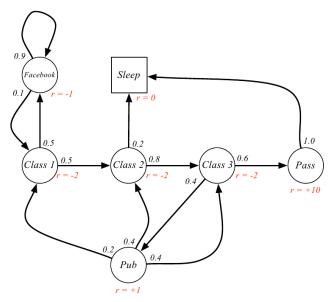

Markov Reward Process

A Markov Reward Process (MRP) is a Markov chain with state costs (rewards) defined by a tuple $(\mathcal{X}, p_{0|0}, p_f, g, \gamma)$

- $\blacktriangleright~\mathcal{X}$ is a discrete/continuous set of states
- $p_{0|0}$ is a prior pmf/pdf defined on \mathcal{X}
- *p_f*(· | *x_t*) is a conditional pmf/pdf defined on *X* for given *x_t* ∈ *X* and summarized by a matrix *P_{ij}* := *p_f*(*i* | *x_t* = *j*) in the finite-dimensional case.
- ▶ g(x) is a function specifying the cost (reward) of state $x \in X$
- $\gamma \in [0,1]$ is a discount factor

Example: Student Markov Reward Process

Cumulative Cost

Value function: The cumulative cost (reward) of an MRP $(\mathcal{X}, p_f, g, \gamma)$ starting from state $x \in \mathcal{X}$ at time 0:

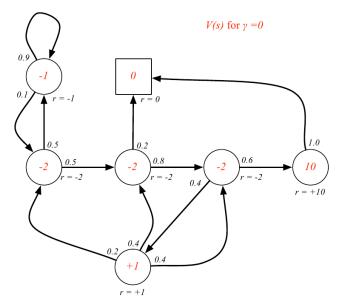

Finite-horizon:
$$J_0(x) := \mathbb{E} \left[g_T(x_T) + \sum_{t=0}^{T-1} g(x_t) \mid x_0 = x \right]$$

Discounted Infinite-horizon: $J(x) := \mathbb{E}\left[\sum_{t=0}^{\infty} \gamma^t g(x_t) \mid x_0 = x\right]$

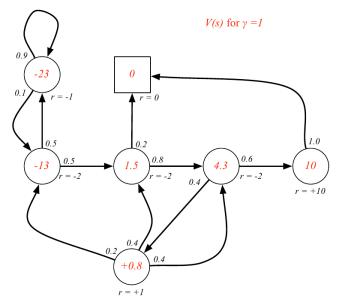

• Average-reward:
$$J(x) := \lim_{T \to \infty} \frac{1}{T} \mathbb{E} \left[\sum_{t=0}^{T-1} g(x_t) \mid x_0 = x \right]$$

- The **discount factor** γ specifies the present value of future costs:
 - \triangleright γ close to 0 leads to myopic/greedy evaluation
 - \triangleright γ close to 1 leads to nonmyopic/far-sighted evaluation
 - Mathematically convenient since it avoids infinite costs as $T \to \infty$
 - The long-term future may be hard to model anyways
 - Animal/human behavior shows preference for immediate reward
 - It is possible to use an undiscounted MRP if all sequences terminate (first-exit formulation). The finite-horizon formulation is a special case of the first-exit formulation.

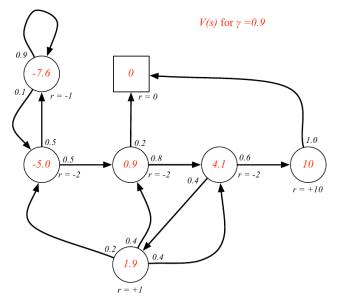

Example: Cumulative Reward of the Student MRP

Example: Cumulative Reward of the Student MRP

Example: Cumulative Reward of the Student MRP

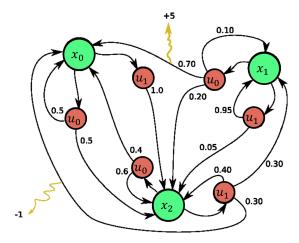

Markov Decision Process

A Markov Decision Process (MDP) is a Markov Reward Process with controlled transitions defined by a tuple $(\mathcal{X}, \mathcal{U}, p_{0|0}, p_f, g, \gamma)$

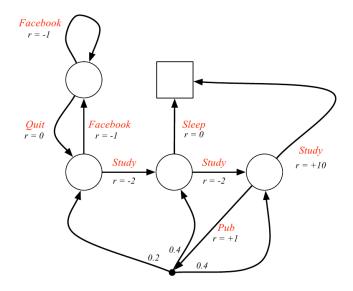

- \mathcal{X} is a discrete/continuous set of states
- $\blacktriangleright~\mathcal{U}$ is a discrete/continuous set of controls
- $p_{0|0}$ is a prior pmf/pdf defined on \mathcal{X}
- *p_f*(· | *x_t*, *u_t*) is a conditional pmf/pdf defined on X for given *x_t* ∈ X and *u_t* ∈ U and summarized by a matrix *P^u_{ij}* := *p_f*(*i* | *x_t* = *j*, *u_t* = *u*) in the finite-dimensional case.
- g(x, u) is a function specifying the cost (reward) of applying control u ∈ U in state x ∈ X
- $\gamma \in [0,1]$ is a discount factor

Example: Markov Decision Process

An action u_t ∈ U(x_t) applied in state x_t ∈ X determines the next state x_{t+1} and the obtained cost (reward) g(x_t, u_t)

Example: Student Markov Decision Process

Control Policy and Cumulative Cost

- Admissible control policy: a sequence π_{0:T−1} of functions π_t that map a state x_t ∈ X to a feasible control input u_t ∈ U(x_t)
- Value function: the cumulative cost (reward) of a policy π applied to an MDP (X, U, p_f, g, γ) with initial state x ∈ X at time t = 0:

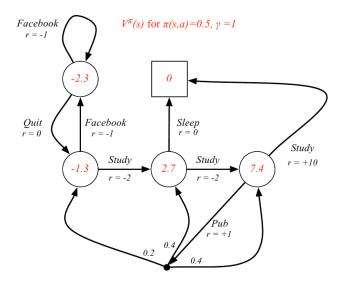

Finite-horizon:
$$J_0^{\pi}(x) := \mathbb{E} \left[\underbrace{g_T(x_T)}_{\text{terminal cost}} + \sum_{t=0}^{T-1} g(x_t, \pi_t(x_t)) \mid x_0 = x \right]$$

► Discounted Infinite-horizon: $J^{\pi}(x) := \mathbb{E}\left[\sum_{t=0}^{\infty} \gamma^{t} g(x_{t}, \pi(x_{t})) \mid x_{0} = x\right]$

• Average-reward:
$$J^{\pi}(x) := \lim_{T \to \infty} \frac{1}{T} \mathbb{E} \left[\sum_{t=0}^{T-1} g(x_t, \pi(x_t)) \mid x_0 = x \right]$$

▶ **Note**: we will show that as $T \to \infty$, optimal policies become stationary, i.e., $\pi := \pi_0 \equiv \pi_1 \equiv \cdots$, and independent of x_0

Example: Value Function of Student MDP

Alternative Cost Formulations

Noise-dependent costs: a more general model allows the stage costs g' to depend on the motion noise w_t:

$$J_0^{\pi}(x) := \mathbb{E}_{w_{0:T}, x_{1:T}} \left[g_T(x_T) + \sum_{t=0}^{T-1} g'(x_t, \pi_t(x_t), w_t) \mid x_0 = x \right]$$

This is equivalent to our formulation since the pdf $p_w(\cdot | x_t, u_t)$ of w_t is known and we can always compute:

$$g(x_t, u_t) := \mathbb{E}_{w_t \mid x_t, u_t} \left[g'(x_t, \pi_t(x_t), w_t) \right] = \int g(x_t, \pi_t(x_t), w_t) p_w(w_t \mid x_t, u_t) dw_t$$

▶ Joint cost-state pdf: a more general model allows random costs g' by specifying the joint pdf p(x', g' | x, u). This is equivalent to our formulation as follows:

$$p_f(x' \mid x, u) := \int p(x', g' \mid x, u) dg'$$
$$g(x, u) := \mathbb{E} \left[g' \mid x, u \right] = \int \int g' p(x', g' \mid, x, u) dx' dg'$$

Comparison of Markov Models

	observed	partially observed
uncontrolled	Markov Chain/MRP	HMM
controlled	MDP	POMDP

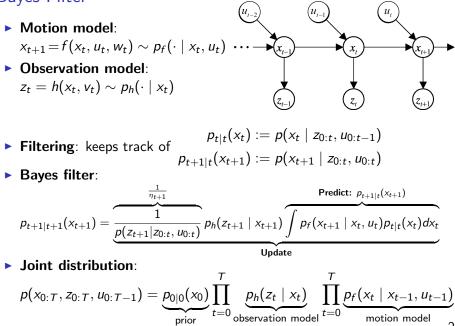

- Markov Chain + Partial Observability = HMM
- Markov Chain + Control = MDP
- Markov Chain + Partial Observability + Control = HMM + Control = MDP + Partial Observability = POMDP

Partially Observable Markov Decision Process

A Partially Observable Markov Decision Process (POMDP) is a Markov Decision Process with partially observable states defined by a tuple $(\mathcal{X}, \mathcal{U}, \mathcal{Z}, p_{0|0}, p_f, p_h, g, \gamma)$

- $\blacktriangleright~\mathcal{X}$ is a discrete/continuous set of states
- $\blacktriangleright~\mathcal{U}$ is a discrete/continuous set of controls
- $\blacktriangleright~\mathcal{Z}$ is a discrete/continuous set of observations
- $p_{0|0}$ is a prior pmf/pdf defined on \mathcal{X}
- *p_f*(· | *x_t*, *u_t*) is a conditional pmf/pdf defined on X for given *x_t* ∈ X and *u_t* ∈ U and summarized by a matrix *P^u_{ij}* := *p_f*(*i* | *x_t* = *j*, *u_t* = *u*) in the finite-dimensional case.
- ▶ $p_h(\cdot | x_t)$ is a conditional pmf/pdf defined on \mathcal{Z} for given $x_t \in \mathcal{X}$ and summarized by a matrix $O_{ij} := p_h(i | x_t = j)$ in the finite-dim case.
- g(x, u) is a function specifying the cost (reward) of applying control u ∈ U in state x ∈ X
- $\gamma \in [0,1]$ is a discount factor

Bayes Filter

Information Space and Sufficient Statistics

- The information available to the robot at time t to choose the control input ut is it := (z_{0:t}, u_{0:t-1}) ∈ I
- The information space I is the space of sequences of observations and controls
- A statistic y_t = s(i_t) is a function of the information available at time t to estimate x_t
- ► The statistic y_t = s(i_t) is sufficient for x_t if the conditional distribution of x_t given the statistic y_t does not depend on the information i_t
- ► Under the Markov and measurement and motion noise independence (over time, from the state, and from each other) assumptions, the distribution of the state x_t conditioned on the information state i_t is a sufficient statistic for x_t. In other words, p_{t|t}(x_t) := p(x_t | i_t) is a compact representation of i_t.

Equivalence of POMDPs and MDPs

• The **Bayes filter** ψ tracks precisely the needed sufficient statistic:

$$p(x_t \mid i_t) = \boxed{p_{t|t}(x_t) = \psi(p_{t-1|t-1}, u_{t-1}, z_t)}_{= \frac{1}{\eta_t} p_h(z_t \mid x_t) \int p_f(x_t \mid x_{t-1}, u_{t-1}) p_{t-1|t-1}(x_{t-1}) dx_{t-1}}$$

• Because $p_{t|t}$ is a sufficient statistic for x_t , we can convert a POMDP $(\mathcal{X}, \mathcal{U}, \mathcal{Z}, p_f, p_h, g, \gamma)$ into an equivalent MDP $(\mathcal{B}, \mathcal{U}, p_{\psi}, \rho, \gamma)$ where:

- ► The state space B := P(X) is the continuous space of pdfs/pmfs over X, e.g., if |X| = N, then B = {b ∈ [0, 1]^N | 1^Tb = 1}
- ► The transformed motion model is the Bayes filter $b_{t+1} = \psi(b_t, u_t, z_t)$, where z_t plays the role of noise or in probabilistic terms:

$$p_{\psi}(b_{t+1} \mid b_t, u_t) := \int \mathbb{1}\{b_{t+1} = \psi(b_t, u_t, z)\} \eta(z \mid b_t, u_t) dz$$
$$\eta(z \mid b_t, u_t) := \int \int p_h(z \mid x_{t+1}) p_f(x_{t+1} \mid x_t, u_t) b_t(x_t) dx_t dx_{t+1}$$

► The transformed stage reward function $\rho(b, u) = \int g(x, u)b(x)dx$ is the expected stage reward

The Problem of Acting Optimally in a POMDP

An infinite-dimensional dynamic optimization problem defined for a POMDP (X, U, Z, p_f, p_h, g, γ) as follows:

$$\min_{\pi_{0:T-1}} \mathbb{E}\left[\gamma^{T}g_{T}(x_{T}) + \sum_{t=0}^{T-1}\gamma^{t}g_{t}(x_{t}, u_{t})\right]$$

s.t. $x_{t+1} \sim p_{f}(\cdot \mid x_{t}, u_{t}), \quad t = 0, \dots, T-1$
 $z_{t+1} \sim p_{h}(\cdot x_{t}), \quad t = 0, \dots, T-1$
 $u_{t} \sim \pi_{t}(\cdot \mid i_{t}), \quad t = 0, \dots, T-1$
 $x_{0} \sim b_{0}(\cdot) \equiv \text{prior pdf over the hidden state } x_{0}$

• Equivalently, using the information-space MDP $(\mathcal{B}, \mathcal{U}, p_{\psi}, \rho, \gamma)$ with sufficient statistic b_t :

$$\min_{\pi_{0:T-1}} J_0^{\pi}(b_0) = \mathbb{E} \left[\gamma^T \rho_T(b_T) + \sum_{t=0}^{T-1} \gamma^t \rho_t(b_t, u_t) \right]$$

s.t. $b_{t+1} = \psi(b_t, u_t, z_{t+1}), \quad t = 0, \dots, T-1$
 $z_{t+1} \sim \eta(\cdot \mid b_t, u_t), \quad t = 0, \dots, T-1$
 $u_t \sim \pi_t(\cdot \mid b_t), \quad t = 0, \dots, T-1$

Final Problem Formulation

- Due to the equivalence between POMDPs and (information-space) MDPs, we will focus exclusively on MDPs
- First, we will consider the finite-horizon formulation

$$\min_{\pi} J_0^{\pi}(x_0) := \mathbb{E}_{x_{1:T}} \left[g_T(x_T) + \sum_{t=0}^{T-1} g_t(x_t, \pi_t(x_t)) \ \middle| \ x_0 \right]$$

s.t. $x_{t+1} \sim p_f(\cdot \mid x_t, \pi_t(x_t)), \qquad t = 0, \dots, T-1$
 $x_t \in \mathcal{X}, \ \pi_t(x_t) \in \mathcal{U}(x_t)$

> Then, we will consider the discounted **infinite-horizon** formulation:

$$\min_{\pi} J^{\pi}(x_0) := \mathbb{E} \left[\sum_{t=0}^{\infty} \gamma^t g(x_t, \pi(x_t)) \mid x_0 \right]$$

s.t. $x_{t+1} \sim p_f(\cdot \mid x_t, \pi_t(x_t)),$
 $x_t \in \mathcal{X}, \ \pi_t(x_t) \in \mathcal{U}(x_t)$

Open Loop vs Closed Loop Control

- There are two different control methodologies:
 - ▶ Open loop: control inputs u_{0:T-1} are determined at once at time 0 as a function of x₀ (fully observable case) or p_{0|0} (partially observable case)
 - Closed loop: control inputs are determined "just-in-time" as a function of the state x_t (fully observable case) or measurement history z_{0:t}, u_{0:t-1} (partially observable case)
- A special case of closed loop control is to simply disregard state/measurement information (open loop control). Thus, open loop control can never give better performance than closed loop control.
- In the absence of disturbances (or in the special linear quadratic Gaussian case), the two give theoretically the same performance.
- When good models are available, open-loop control is a viable strategy for short time horizons

Open Loop vs Closed Loop Control

- Open loop control is typically much less demanding than closed loop control
- ► Consider a discrete-space example with N_x = 10 states, N_u = 10 control inputs, planning horizon T = 4, and given x₀:
 - There are $N_u^T = 10^4$ different open-loop strategies
 - ► There are N_u(N^{N_x})^{T-1} = N^{N_x(T-1)+1} = 10³¹ different closed-loop strategies (10 orders of magnitude larger than the number of stars in the observable universe!)

Example: Chess Strategy Optimization

- Objective: come up with a strategy that maximizes the chances of winning a 2 game chess match.
- Possible outcomes:
 - Win/Lose: 1 point for the winner, 0 for the loser
 - Draw: 0.5 points for each player
 - If the score is equal after 2 games, the players continue playing until one wins (sudden death)
- Playing styles:
 - **Timid**: draw with probability p_d and lose with probability $(1 p_d)$
 - **Bold**: win with probability p_w and lose with probability $(1 p_w)$
 - Assumption: $p_d > p_w$

Finite-state Model of the Chess Match

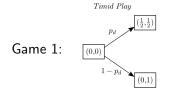

- The state x_t is a 2-D vector with our and the opponent's score after the t-th game
- ▶ The **control** *u*_t is the play style: timid or bold
- The **noise** w_t is the score of the next game
- ► Since timid play does not make sense during the sudden death stage, the planning horizon is T = 2
- We can construct a time-dependent motion model P^u_{ijt} for t ∈ {0,1} (shown on the next slide)

► **Cost**: minimize loss probability: $-P_{win} = \mathbb{E}_{x_{1:2}} \left[g_2(x_2) + \sum_{t=0}^{1} g_t(x_t, u_t) \right]$

where $g_t(x_t, u_t) = 0$ for $t \in \{0, 1\}$ and

$$g_2(x_2) = \begin{cases} -1 & \text{if } x_2 = \left(\frac{3}{2}, \frac{1}{2}\right) \text{ or } (2,0) \\ -p_w & \text{if } x_2 = (1,1) \\ 0 & \text{if } x_2 = \left(\frac{1}{2}, \frac{3}{2}\right) \text{ or } (0,2) \end{cases}$$
29

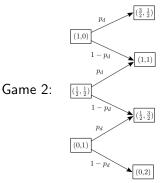

Chess Transition Probabilities

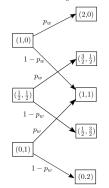

Bold Play

Open Loop Chess Strategy

There are 4 admissible open-loop policies:

- 1. timid-timid: $P_{win} = p_d^2 p_w$ 2. bold-bold: $P_{win} = p_w^2 + p_w(1 - p_w)p_w + (1 - p_w)p_w p_w = p_w^2(3 - 2p_w)$ 3. bold-timid: $P_{win} = p_w p_d + p_w(1 - p_d)p_w$ 4. timid-bold: $P_{win} = p_d p_w + (1 - p_d)p_w^2$
- ▶ Since $p_d^2 p_w \le p_d p_w \le p_d p_w + (1 p_d) p_w^2$, timid-timid is not optimal
- The best achievable winning probability is:

$$P_{win}^{*} = \max\{p_{w}^{2}(3-2p_{w}), p_{d}p_{w} + (1-p_{d})p_{w}^{2}\} = p_{w}^{2} + p_{w}(1-p_{w})\max\{2p_{w}, p_{d}\}$$

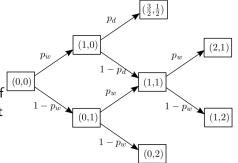

▶ In the open-loop case, if $p_w \leq 0.5$, then $P_{win}^* \leq 0.5$

For
$$p_w = 0.45$$
 and $p_d = 0.9$, $P^*_{win} = 0.43$

- For $p_w = 0.5$ and $p_d = 1.0$, $P_{win}^* = 0.5$
- If p_d > 2p_w, bold-timid and timid-bold are optimal open-loop policies; otherwise bold-bold is optimal

Closed Loop Chess Strategy

- There are 16 admissible policies
- Consider one option: play timid if and only if ahead (it will turn out that this is optimal)

- The probability of winning is: $P_{win} = p_d p_w + p_w((1-p_d)p_w + p_w(1-p_w)) = p_w^2(2-p_w) + p_w(1-p_w)p_d$
- Note that in the closed-loop case we can achieve P_{win} larger than 0.5 even when p_w is less than 0.5:

• For
$$p_w = 0.45$$
 and $p_d = 0.9$, $P_{win} = 0.5$

• For $p_w = 0.5$ and $p_d = 1.0$, $P_{win} = 0.625$
